## The Diehard Tests

- ▶ The diehard tests are a battery of statistical tests for measuring the quality of a random number generator.
- ▶ They were developed by George Marsaglia over several years and first published in 1995 on a CD-ROM of random numbers.

# Diehard Tests

**Birthday spacings:** Choose random points on a large interval. The spacings between the points should be asymptotically exponentially distributed.

The name is based on the birthday paradox.

**Overlapping permutations:** Analyze sequences of five consecutive random numbers. The 120 possible orderings should occur with statistically equal probability.

# Diehard Tests

**Ranks of matrices:** Select some number of bits from some number of random numbers to form a matrix over 0,1, then determine the rank of the matrix. Count the ranks.

**Monkey tests:** Treat sequences of some number of bits as "words". Count the overlapping words in a stream. The number of "words" that don't appear should follow a known distribution.  
The name is based on the *infinite monkey* theorem.

# Diehard Tests

**Count the 1s:** Count the 1 bits in each of either successive or chosen bytes.

Convert the counts to "letters", and count the occurrences of five-letter "words".

**Parking lot test:** Randomly place unit circles in a  $100 \times 100$  square. If the circle overlaps an existing one, try again. After 12,000 tries, the number of successfully "parked" circles should follow a certain normal distribution.

# Diehard Tests

**Minimum distance test:** Randomly place 8,000 points in a 10,000 x 10,000 square, then find the minimum distance between the pairs.

The square of this distance should be exponentially distributed with a certain mean.

**Random spheres test:** Randomly choose 4,000 points in a cube of edge 1,000.

Center a sphere on each point, whose radius is the minimum distance to another point.

The smallest sphere's volume should be exponentially distributed with a certain mean.

# Diehard Tests

**The squeeze test:** Multiply 231 by random floats on  $(0,1)$  until you reach 1. Repeat this 100,000 times. The number of floats needed to reach 1 should follow a certain distribution.

**Overlapping sums test:** Generate a long sequence of random floats on  $(0,1)$ .  
Add sequences of 100 consecutive floats.  
The sums should be normally distributed with characteristic mean and sigma.

# Diehard Tests

**Runs test:** Generate a long sequence of random floats on  $(0,1)$ . Count ascending and descending runs. The counts should follow a certain distribution.

**The craps test:** Play 200,000 games of craps, counting the wins and the number of throws per game. Each count should follow a certain distribution.
